

Figure 1 is a bar chart showing the mean bias of various climate models across different values of L (1, 3, 6). The y-axis represents the mean bias, ranging from -2.0 to 0.5. The x-axis shows $L = 1$, $L = 3$, and $L = 6$. For each L , there are eight bars representing different models: climatology (blue), persistence (orange), ar (green), ols (red), ridge (purple), lasso (brown), elasticnet (pink), and xgboost (yellow). Each bar is accompanied by a vertical error bar representing the standard deviation. The climatology model shows a significant negative bias for $L=1$, which decreases as L increases. The other models show positive biases that are relatively stable across L values.
